

Chemistry 236 -- Quiz 2

Lab Day _____

September 29, 2010 — Least Squares and Probability Distributions

Pledge and signature:

Note: If you want your paper returned folded (i.e., score concealed), please print your name on the back.

1. (7) Consider the probability distribution, $P(x) = c (1 - x)$, defined over the range $0 \leq x \leq 1$. For this distribution, calculate: (a) the normalization constant, (b) the mean, (c) the variance, and (d) the standard deviation.

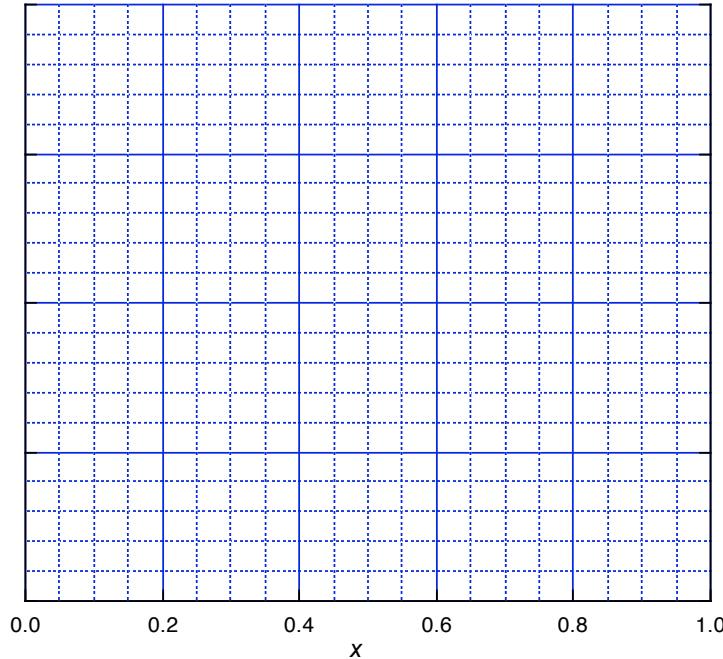

2. (6) Suppose you generate 10^5 random numbers using this distribution.

(a) How many would you expect to fall within the x range 0.40–0.50? And what is the standard deviation of this value?

(b) If you now generate 10^5 averages of 8 such random numbers, what is the expected mean and standard deviation for these averages?

3. (5) Briefly sketch on the provided grid the *shapes* of the following probability distributions (*i.e.*, don't worry about the *y*-axis scale). Label your curves clearly.

- (a) $P(x)$ from Prob. 1 above;
- (b) what you expect if you average 20 random deviates from this same $P(x)$; and
- (c) what you observed in KG4 when you histogrammed averages of 2 uniform random deviates.

4. (8) **Least Squares and KaleidaGraph.**

(a) We often fit data to polynomials in x or in $(x - x_0)$ (x_0 a constant) to achieve a smooth representation of data. Suppose you have fitted data, unweighted, to such a function. When do these results tell you that dropping a term will yield a smaller s_y^2 , hence a statistically better fit?

(b) Suppose you fit thermistor calibration data for the region 19-34° to a quadratic polynomial. How can you define this fit so as to easily obtain the calibration correction at 29° *and* its uncertainty?

(c) Write **exactly** what you should enter in the **Define Fit** box to fit your sums of 12 uniform random deviates to a Gaussian function. [gf(x) NOT adequate here!] What values should you obtain (approximately) for the parameters that govern the *location* and *width* of the distribution?
